PREFACE

This research was conducted under the sponsorship of the Department of Housing and Urban Development by the Applied Economics Group, of the Center for Building Technology, at the National Engineering Laboratory, National Bureau of Standards. This report provides public and private decision makers with a computerized procedure for estimating the costs of lead-based paint abatement. This procedure is based on lead-based paint abatement cost figures collected during an extensive field test program in which lead-based paint hazard abatement activities were carried out in approximately 200 dwelling units.

Appreciation is extended to Dr. Harold. E. Marshall, Applied Economics Group, and Dr. John S. McConnaughey, formerly with the Applied Economics Group, who reviewed the economic aspects of this paper. Appreciation is also extended to Mssrs. William G. Hall, Center for Applied Mathematics, and A. Philip Cramp and David Waksman, Center for Building Technology, for their many helpful comments concerning the treatment of certain technical issues presented in the paper. Special appreciation is extended to Dr. Joseph G. Kowalski, formerly with the Applied Economics Group, whose stimulating discussions provided guidance and encouragement throughout this effort.

ABSTRACT

This report describes a computerized procedure for estimating the cost of eliminating the lead-based paint hazard from buildings. This procedure is based on the results of an extensive field test program in which lead-based paint hazard abatement activities were carried out in approximately 200 dwelling units in three cities. The computerized cost estimation procedure which emerged is particularly useful because it takes into consideration both variations in the condition of the dwelling unit as well as in the prices for labor and materials. As a result, it permits the least costly abatement technique to be identified under a wide variety of circumstances. In addition, when contract cost estimates are desired, the computer program groups dwelling units together into contracts in such a way that the sum of the expected bid prices is minimized.

This report is intended to serve as a user's manual for local programs concerned with the problem of estimating lead-based paint abatement costs. Specific cases with respect to the preparation of cost estimates for individual dwelling units or of budget estimates for program managers, policy makers, or other decision makers, are treated.

Keywords: Applied economics; building economics; building materials; economic analysis; housing; lead-based paint; lead poisoning.

1. INTRODUCTION

Through the "Lead-Based Paint Poisoning Prevention Act" of 1971, Congress has delegated to the Department of Housing and Urban Development the leadership role in developing the technical information needed to determine procedures which will improve the efficiency with which funds are allocated to eliminate high levels of lead-based paint (LBP) in housing. To accomplish this goal the Experimental Hazard Elimination Program (EHEP) was formulated by the Department of Housing and Urban Development with the technical assistance of the National Bureau of Standards. In this program 20 LBP hazard abatement techniques were demonstrated in approximately 200 dwelling units in Washington, D.C., Atlanta, Georgia, and Boston, Massachusetts. EHEP was divided into two phases. The first phase was carried out in Washington, D.C., and Atlanta, Georgia. Phase II was carried out in Boston. Phase II differed from Phase I in that an experimental design was rigorously defined and controlled so that variations in abatement technique costs could be analyzed with regard to such important factors as type and condition of housing as well as prevailing supply and demand conditions for construction skills and materials. EHEP was intended to help accomplish the goal mentioned above in four ways. First, it enabled the experimental LBP abatement techniques to be evaluated in field deleading operations. Second, through the collection of cost data, it established a framework for estimating the costs of future LBP hazard abatement operations. Third, it provided a data base against which procedures for estimating abatement costs could be tested for accuracy and ease of application. Fourth, through the development of procedures for estimating LBP abatement costs, it permitted a computer time-sharing program which identifies the least-cost means for eliminating the LBP hazard from a dwelling unit to be developed.

1.1 Purpose

The purpose of this report is to describe the computerized cost estimating procedure, identify its data requirements, show how it may be run on a time-sharing terminal, and provide guidelines for interpreting its output. The computerized cost estimating procedure is particularly useful because it takes into consideration variations in the condition of the dwelling unit as well as in the prices for labor and materials. As a result, it permits the least costly abatement technique to be identified for each set of considerations. Two types of estimates are possible with the computerized procedure. First, the procedure may be used to develop a baseline forecast for an overall program. These estimates will of necessity be only crude guidelines for budgetary purposes. The second type of estimate is referred to as a contract cost estimate.

Contract cost estimates are based on dwelling unit specific information and are much more reliable. Past empirical studies have demonstrated

that if dwelling unit specific information is used, estimated costs are usually within 5 to 10 percent of the actual cost. In addition, when contract cost estimates are desired, the computer program groups dwelling units together into contracts in such a way that the sum of the expected bid prices is minimized.

This report is intended to serve as a user's manual for those who are concerned with the problem of estimating LBP abatement costs. Specific cases with respect to the preparation of cost estimates for individual dwelling units or of budget estimates for program managers, policy makers, or other decision makers, are treated. Throughout this report the emphasis is placed on how the procedure can be used to estimate LBP abatement costs under a wide variety of circumstances.

1.2 Scope and Approach

The general plan of this report is to briefly describe the computer program, state the requirements of the program, and show how the computer program may be accessed. Specifically this user's manual is organized as follows:

Chapter 2 describes the computer program, its capabilities and its limitations. The data requirements for using the computerized procedure to estimate abatement costs at the individual dwelling unit level and for forecasting the costs of a major LBP abatement program are then identified. Guidelines are also given on how and where to obtain the necessary data should it not already be available. A description of how the computer program identifies the least-costly abatement technique follows. Next an explanation is given of how the computer program groups dwelling units into contract packages in such a way that the sum of the bid prices is minimized. The case in which cost estimates for a major abatement program are required is then treated.

Chapter 3 introduces the user to the Federal Agencies' Computer Time-Sharing System's (FACTS) library of programs. A step by step procedure for running the program via FACTS and interpreting its output is then given.

This report also contains four technical appendices. These appendices provide background information in three subject areas.

Appendix A discusses some of the engineering properties of the various LBP abatement techniques. It is included as a guide to when and where the application of a particular LBP abatement technique would be appropriate.

Appendix B extends the discussion of the FACTS library of programs to include a detailed description of how the user enters the FACTS library and establishes a user file.

Appendix C provides examples of what the actual input and output statements from the computer terminal should look like. Sample computer runs are given to show how this procedure can be used to provide (1) baseline cost estimates for a major abatement program, and (2) contract or individual dwelling unit cost estimates.

Appendix D consists of a listing of the computer program as it is stored in the FACTS library.

Although the results of the computerized cost estimation procedure are based on information which can be readily measured or checked, it is important to point out that some judgmental decisions are inevitable. There is no substitute for professional experience. The use of this procedure is not intended to do away with input from experienced individuals but to complement it. However, the use of this procedure does reduce to a minimum the reliance on decisions which are purely judgmental and hence can neither be confirmed nor denied. Thus a real strength of this procedure is being able to quickly identify any discrepancies should they result, determine how serious they are and take them into consideration in future cost estimates.

2. DESCRIPTION OF THE COMPUTER PROGRAM

The computer program discussed in this chapter is written in the BASIC¹ language. Although the program is written in BASIC it is not necessary for the user to know how to use BASIC in order to run the program. The program is designed to provide a maximum amount of flexibility to the user and includes many check mechanisms which significantly reduce the chance of a user error. The program itself includes a procedure for calculating the expected costs (installation, overhead and profit) of six methods of covering over LBP on wall surfaces and ceilings², four methods of paint removal on trim surfaces³, and the replacement of defective or deteriorated doors, door frames, or windows and frames. The six barrier materials analyzed in the computer program are: 1) cementitious coating, 2) gypsum veneer plaster; 3) gypsum wallboard, 4) cement-coated fiberglass, 5) plywood paneling, and 6) vinyl-coated fabric. The four paint removal methods are: 1) electrical heat gun; 2) infrared-heating device; 3) hand scraping; and 4) solvent-based paint remover. Two types of cost estimates are possible with the computer program.

¹ BASIC is an acronym for Beginner's All-purpose Symbolic Instruction Code. A good introduction to BASIC is given in D. Spencer, A Guide to BASIC Programming: A Time-Sharing Language, Addison-Wesley Publishing Company, Inc., Reading, Mass., 1970.

² Five additional methods for covering over LBP on wall surfaces and ceilings are discussed in Appendix A.

³ Two additional paint removal methods are discussed in Appendix A.

In the first type, the program permits the user to input specific information on anticipated contract packages of dwelling units. (For example, the square feet of wall area, linear feet of trim, and number of doors, frames and windows requiring treatment.) The program then identifies the least-cost combination of abatement techniques for each dwelling unit. The original "set" of dwelling units is then divided up in such a way that the sum of the expected bid prices of the resultant "contract packages" is minimized. The expected bid price and the markup ratio for each contract is then printed out as are the dwelling units in that contract. This information is most useful in the short term planning or scheduling of LBP abatement activities

In the second type, the user inputs information on representative or "statistical" dwelling units for a given dwelling unit type and age category. The computer program calculates the expected costs for each technique and then averages them. It then prints out the expected cost for wall and trim abatement and the markup ratio. If the dwelling unit's age/type category (e.g., Pre 1940 single family attached) was identified, it is also printed out. This information may be used to make baseline estimates for planning purposes, budgetary allocations and other long range activities upon which LBP abatement work might impinge.

2.1 What the Computer Program Does

As a first step in seeing what the computer program does, we shall refer to Diagram 2.1. Diagram 2.1 is a flowchart of the computer program; it shows the basic input requirements, the sequence in which calculations take place, and the program outputs.

Notice that there are two "branches" in Diagram 2.1. One branch treats the case where cost estimates for a major program are desired. The second branch deals with cases in which cost estimates for individual dwelling units or contract packages are desired. Since both branches of the flowchart are the same up to block A, we shall assume that the computer program has already been called up and data on wage rates and material prices entered. In the description which follows, the term "key factor" is used to denote a specific piece of information which affects abatement technique cost or markup.

Suppose the user enters a 1 in block A (see Diagram 2.1), indicating that a cost estimate for a major LBP abatement program is desired. The computer will then request information on the "statistical" dwelling unit. Detailed discussions of the term "statistical" dwelling unit are presented in Sections 2.2 and 2.4. Once all data have been entered, the computer calculates the direct costs for each wall and trim technique based on the representative ("statistical") values of the key factors. These direct cost figures are then averaged. A markup ratio based on the representative values of the key factors

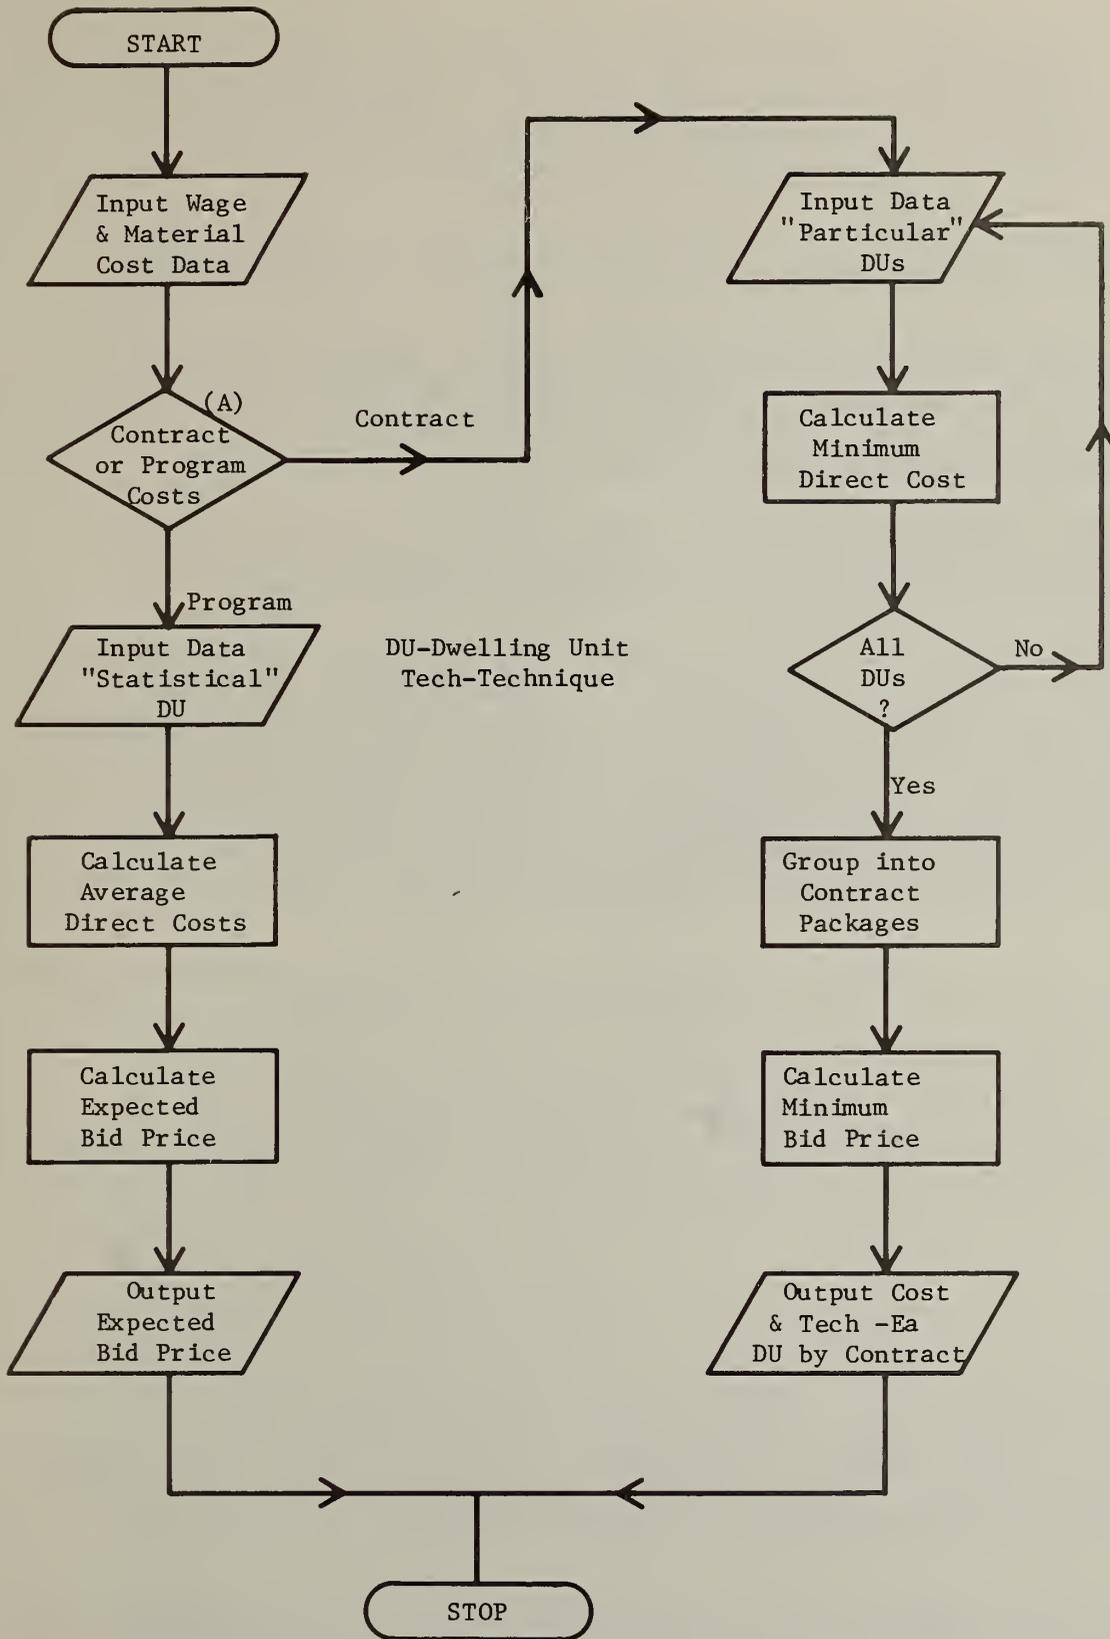

DIAGRAM 2.1

FLOWCHART FOR COMPUTER TIME-SHARING PROGRAM

is also calculated. (The markup ratio assumes that, on the average, three dwelling units will be in each contract.¹) The markup ratio is then used to calculate the total cost (i.e., the sum of direct costs, overhead costs, and profit) of deleading the "statistical" dwelling unit. The user may then use this figure to determine the costs of that portion of the deleading program. Once the cost information has been printed out, the user has the option of either stopping or performing cost estimates for other categories (building type/age).

In the event that the user wished to make contract cost estimates, the computer program would operate in a slightly different manner. However, before explaining this section of the flowchart, it is important to recognize several constraints. First, the user should place the dwelling units into groups of from one to ten dwelling units.²

Second, all dwelling units within a group should be relatively close to each other so that the distance between dwelling units will not enter as a complicating factor in making up contract packages.

Let us now return to the flowchart. In response to the computer's question in block A, a 0 is entered, to indicate that contract cost estimates are desired. (Recall from the previous discussion that information on wage rates and material prices would have been entered prior to reaching block A). The computer then asks for how many dwelling units the user will be inputting data. Suppose the user has eight dwelling units for which he wants cost estimates. The computer first requests information on all the dwelling unit specific key factors for

¹ The size of the contract package used in the "program" portion of the computerized procedure is closely related to the economic concept of economies of scale. In brief there are two types of economies of scale. They are: 1) intra-unit (increasing the number of square feet, linear feet or components in a given dwelling unit) scale economies; and 2) inter-unit (increasing the number of dwelling units in the contract) scale economies. Although intra-unit scale economies exert a strong and favorable effect on the costs of LBP hazard abatement, the effects of inter-unit scale economies exert a perverse impact on abatement costs. This is primarily due to the fact that the contractors who perform LBP abatement work tend to be rather small. Consequently, carrying out work in a large number of dwelling units may result in coordination and scheduling problems which significantly increase costs. Past empirical studies have concluded that it is wise to keep contract packages small. (For an in depth discussion of this topic see Robert E. Chapman and Joseph G. Kowalski, Lead Paint Abatement Costs: Some Technical and Theoretical Considerations, National Bureau of Standards, Technical Report 979, February 1979.)

² The computer will not accept information on more than ten dwelling units at any one time. Thus if 50 dwelling units required deleading, at least five groups of ten dwelling units would have to be formed.

dwelling unit number one. The cost of each abatement technique is then calculated and the one which minimizes direct costs is identified. (This procedure is followed for both wall and trim surfaces.) The computer then returns to the user and requests information on the second dwelling unit.

This input loop continues until all data regarding specific dwelling units have been input. As a next step, the computer groups the dwelling units into "preliminary" contract packages based on the values of the key factors and other decision criteria implicit in the program. The objective here is to reduce the expected markup ratio to as small a number as possible. The computer program then tests to see if the sum of the expected bid prices for the "preliminary" contract packages can be reduced by removing a dwelling unit from one contract package and placing it in another. Once this search routine finds that no further reductions in the overall bid price can be achieved, the dwelling units are assigned to contract packages and the program enters the output routine. The output routine first prints the least-cost technique for both wall and trim surfaces for each dwelling unit and gives expected cost. This is done for each contract (see Appendix C for an example). For example, the first contract might have dwelling units number 1, 3, 6 and 7; the second dwelling units 2 and 8; and the third dwelling units 4 and 5. The expected markup ratio for each contract is also given in order to facilitate policy analysis by program decision makers. (This information is useful for policy analysis because if markup ratios are consistently high, it may be possible to achieve a reduction in program costs by operating in a cost plus fixed fee contracting mode.)

2.2 Requirements of the Computer Program

2.2.1 Data Needs

The first step in applying the EHEP cost models involves determining the minimum data requirements to exercise the models. Through experience gained in EHEP, we have found that data needs can be divided into three basic categories. These categories are:

- (1) data on wage rates;
- (2) data on material prices; and
- (3) data on the dwelling unit.

These three categories reflect job specific requirements as well as prevailing supply and demand conditions in the labor and product markets. (Within each category there may be some variation in the amount of data required to exercise the models for different abatement techniques due to differences in the key factors affecting technique cost.)

Notice that in Table 2.1 the individual labor skills are identified. A close look at Table 2.1 shows that six skill types can be used in LBP abatement activities. It is important to point out that the figure required is the average hourly base wage rate.

Costs for six materials are also needed unless doors, door frames, or windows and frames are to be replaced. The first four materials are associated with LBP abatement techniques applied to walls and ceilings. The materials listed are gypsum wallboard, plywood paneling, vinyl-coated fabric and cement-coated fiberglass. Averages based on recent purchases will usually suffice. In the event that a similar product is used, such as prefinished gypsum wallboard instead of gypsum wallboard, melamine paneling instead of plywood paneling, or gypsum jute instead of cement-coated fiberglass, then its price should be substituted. This flexibility should help in assessing the cost impacts of alternative methods of LBP abatement on expected contract costs. Unless a prefinished product (e.g., plywood paneling) is used, finish painting is usually required; a cost for flat latex and semi-gloss enamel (oil base) is therefore also included.

Data on wages and data on material prices are referred to as contract specific since, unless specific skills or materials are needed in a particular dwelling unit, these data will remain constant for the whole contract package. (In general these data will remain constant over many contracts). This bit of information should prove quite useful to the user of the computer program. This is because it will permit the user to hold this set of prices constant over many computer runs and thus will reduce terminal input requirements. A sample of a worksheet which we have found quite useful in keeping a running tabulation on these data types is shown in Table 2.1. (Since the computer program assumes that any abatement technique "could" be least costly, enough information must be input to insure that an estimate for each technique can be calculated.)

UNFINISHED WINDOW AND FRAME - (NEW - EACH)	_____

Dwelling unit specific data may be divided into two basic types: those concerned with the deleading of walls and ceilings, and those concerned with the deleading of trim surfaces. Specific dwelling unit data which are needed to perform deleading cost estimates for wall areas include:

- the gross square feet of wall area;¹
- the net square feet of wall area;²
- if the wall is in an unsound condition³; if cabinet work or pantry work is to take place; or if wallpaper stripping is to take place.

Dwelling unit data required to perform deleading cost estimates for trim surfaces include:

- the linear feet of windows and frames requiring deleading;
- the linear feet of doors and frames requiring deleading;
- the linear feet of miscellaneous trim requiring deleading; and
- the number and type of windows, doors, door frames, and/or miscellaneous trim requiring replacement.

2.2.2 Obtaining the Necessary Data

Once all of the factors needed to make the desired cost estimate have been identified, it is possible to map out a strategy for systematically and efficiently measuring their values.

¹ The gross square feet of wall area is defined as the total wall area including openings for windows, doors, and cabinets. It is equal to the perimeter of the room times the ceiling height.

² The net square feet of wall area is defined as the wall area remaining after the area for all openings, such as doors, windows and cabinets has been subtracted from the gross square feet of wall area.

³ An unsound wall is defined as any wall which exhibits one or more of the following characteristics: (1) crumbling plaster, (2) bulging, (3) efflorescence, (4) delamination from lath or structure members, and (5) holes greater than four inches in diameter. If none of these five characteristics are present, then the wall is defined as sound. Should the wall require furring prior to the application of a particular barrier material, this cost will have to be added onto the cost of that LBP hazard abatement technique. Previous studies have concluded that such cases should not exceed 10 percent of the total and will most likely be less than 5 percent of the total. See Douglas R. Shier and William G. Hall, Analysis of Housing Data Collected in a Lead-Based Paint Survey in Pittsburgh, Pennsylvania -- Part II, National Bureau of Standards, NBSIR 77-1250, May 1977.

One major source of data which should not be overlooked is the dwelling unit survey. Surveys are almost always conducted at the start of an abatement program to determine the incidence of LBP in housing. Published information on conducting a LBP survey provides us with valuable insight into how the survey can complement the cost estimation effort.¹ The importance of collecting data at this time cannot be overstressed since it permits very detailed information on specific characteristics of the dwelling unit to be documented at little or no extra expense to the overall program. Experience gained during EHEP indicated that a three man team could rapidly survey a dwelling unit and make measurements which greatly enhanced the quality and accuracy of the cost estimates.² One exercise which was particularly useful was the preparation of a floor plan for the dwelling unit being surveyed. It was found that using a piece of graph paper helped the team member sketch the floor plan accurately. One of the other team members then assists in measuring the size of the rooms, the height of the ceiling, the size and location of all doors and windows, window sill height and information on cabinets. It was found that these elements could easily be placed on the floor plan using the standard architectural notations. Another benefit of the LBP survey is that it helps to identify potential problem areas, such as, unsound substrates, deteriorated trim or nonfunctional doors or windows. Careful documentation of this information during the survey permits an estimate of the required repairs and component replacements to be made.

The dwelling unit survey is particularly important when forecasts for the costs of a major LBP abatement program are needed. This is because within most urban areas the housing stock is quite varied. Previous studies have also shown that within this varied stock of housing differing amounts of LBP are expected to be found. Therefore, in order to establish a credible baseline cost estimate, it seems reasonable that forecasts for budgeting, scheduling and other programmatic purposes should take these differences into consideration as much as possible.

Probably the most important step is to divide the housing stock into several well defined types. For example, the following housing types might be used: multifamily low rise, multifamily high rise, single family attached, single family detached one story, single family detached two or more stories. Associated with each housing type would then be an age group. Commonly used age groups are: Pre 1940, 1940 to 1960, and Post 1960. All dwelling units could therefore be grouped into one of these 15 type/age categories. As the survey progresses,

¹ A detailed description of the organization and implementation phases of a dwelling unit survey is given in William G. Hall and Lillian T. Slovic, Survey Manual for Estimating the Incidence of Lead Paint in Housing, National Bureau of Standards, Technical Note 921, September 1976.

² It is anticipated that the members of the survey team can learn enough about what to look for during the survey as part of the inspector training period described in the report by Hall and Slovic.

information collected on individual dwelling units can be used to establish estimates (averages) of the expected amounts of deleading work to take place in any dwelling unit by category (i.e., type and age). These "statistical" dwelling units can then be used to generate baseline cost estimates for the program. For example, if there were 2000 pre 1940 single family attached dwelling units and the expected bid price for deleading the "statistical" pre 1940 single family attached dwelling unit was \$1250, then \$2.5 million would be a good indicator of the expected costs for that portion of the program. The use of "statistical" dwelling units to produce baseline program cost estimates should give program administrators, and other public officials, some insight into the magnitude of the anticipated program, as well as facilitate the scheduling of the actual deleading work. These estimates should also provide the community with a means of gauging the impact that the program will have on the community and, to some extent, the local housing market.

The input data requirements for the computer program discussed in the previous subsections are summarized in Table 2.2.¹

2.3 Contract Cost Estimates

As mentioned earlier, there are two branches, Contract and Program, in the computerized procedure for estimating LBP abatement costs. Although there are several similarities, for example, the same equations are used in estimating the direct cost of each wall and trim technique, the way in which building and economic factors are combined differs significantly between Contract and Program cost estimates. In this section we shall examine the process by which the computer program arrives at a contract cost estimate, where specific dwelling units are to be delead. Section 2.4 will draw on this explanation and highlight the differences between Contract and Program cost estimation.

2.3.1 Determining the Least-Cost Abatement Technique

We have already seen that the direct cost of each wall and trim abatement technique may be estimated with a small number of key factors. These key factors, when combined with certain weighting values, form the basis for the cost estimating equation for a particular abatement technique.²

¹ The term "XRF READING" which appears in Table 2.2 refers to the lead content of the paint film in milligrams per square centimeter (mg/cm^2), as measured by a portable x-ray fluorescence analyzer.

² For further information on the statistical methods used to arrive at these cost equations, see Robert E. Chapman and Joseph G. Kowalski, Lead Paint Abatement Costs: Some Technical and Theoretical Considerations, National Bureau of Standards, Technical Note 979, February 1978.

XRF READING (LEAD CONTENT: mg/cm ²)	FOR EACH TRIM TYPE	FOR EACH TRIM TYPE

In some cases the process of calculating direct costs must be done in two parts. In these cases, the material cost per square foot is computed first based on its own set of key factors. It is used as an input, that is a key factor, in the equation for direct cost per square foot. In some cases direct cost is based on productivity and the average wage rate. The computer program then selects the least costly technique for deleading walls.¹

This same process is followed for the four techniques for deleading trim, with the exception of the fact that there is a separate equation for each trim component (i.e., doors and frames, windows and frames, and miscellaneous trim). The total direct cost is the sum of these components plus finish painting costs. After all dwelling units are completed for this set of estimates, the program moves on to the markup calculation.

2.3.2 Estimating Contract Markup and Forming Contract Packages

In order to get an estimate for markup, a specific contract or collection of dwelling units is needed. In our calculations it is assumed that it would be administratively desirable to have at least two dwelling units in each contract. Furthermore, due to the way the key factors in the markup calculation are combined (some have positive and some have negative effects), certain combinations of two or more dwelling units may actually lower the markup ratio and therefore lower the bid price of that contract.²

To group the dwelling units together in the best possible pairs, the computer program calculates a markup differential applied to the direct cost of every pair of dwelling units, ranks two pairs, and

¹ More specifically, data is input into the computer program on one dwelling unit at a time. Once all necessary data has been input, the program begins by calculating the direct cost per square foot of gypsum wallboard. This value is stored in a special variable where it is then compared with the direct cost of the other wall techniques as the direct cost per square foot for each one is estimated. If the new value is smaller, it is stored in the variable, otherwise the value remains unchanged. The costs of all techniques are estimated and compared in this manner until the least-cost technique for deleading walls is determined. Note that when a switch takes place, the name of the new technique is also stored in a special character variable so that the name of the least-cost method can also be identified. A final step is the multiplication of the per square foot cost by the number of gross square feet of wall area and the addition of any painting costs.

² Again see Robert E. Chapman and Joseph G. Kowalski, Lead Paint Abatement Costs: Some Technical and Theoretical Consideration, National Bureau of Standards, Technical Note 979, February 1979.

chooses those pairs that either reduce markup or cause it to increase as little as possible. If cost estimates are desired for an odd number of dwelling units, the one left after the preliminary two-unit contracts are formed remains in a contract by itself.

The process described above is repeated to see if any further reduction in markup/bid price can be achieved by grouping any of the preliminary two-unit contracts into a four-unit contract or a three-unit contract if costs for an odd number of dwelling units are being estimated. In this iteration, except for the case of a remaining single dwelling unit contract, no grouping takes place unless there is a definite decrease in contractor markup/bid price. If a single-unit contract resulted from the first iteration, it is joined to that other contract which results in the smallest increase in markup/bid price. Once this analysis has been conducted for each of the preliminary contract packages a final assignment will be made. From this point on no dwelling unit will be switched from one contract to another; further reductions in markup/bid price, however, may be possible through a switch in abatement technique. This is the subject of the next section.

2.3.3 Determining the Final Abatement Techniques and Printing Out Results

There is one final test the program performs which has the potential for further reductions in markup/bid price. Because of contractors' general familiarity with gypsum wallboard and plywood paneling, the use of either of these techniques could cause them to lower their markup and, in effect, reduce the bid price. It is necessary then, to determine if substituting gypsum wallboard or plywood paneling for the technique which minimizes direct cost would result in a lower bid price for the contract. In other words, would the reduction in markup more than compensate for the higher per square foot direct cost. The computer performs this comparison by examining direct cost and markup differentials. If the gain (reduction in markup) from a switch to gypsum wallboard or plywood paneling is greater than the cost (higher per square foot direct cost), the original technique is replaced. Otherwise the technique which minimized direct cost is kept, and the program moves on to the next dwelling unit. The program examines each dwelling unit within its particular contract. The process is repeated until all contract packages have been analyzed. The end result of this process may be viewed as a stable solution because no further reductions in bid price can be accomplished. Consequently the sum of the bid prices for each contract may be viewed as the lowest possible for the given values of the relevant key factors.

After deciding on the final abatement techniques and contract packages, the total direct cost and the wall and trim technique chosen for each dwelling unit within a contract is printed out. Finally the contract bid price and markup ratio for each contract is printed. Once this has been done, all cost estimation associated with this set of dwelling units is complete.

2.4 Program Cost Estimates

The computer program may also be used in cases where a program manager or policy maker needs LBP abatement cost estimates for planning or budgetary purposes. The same basic wage and material data used in the contract estimating case are still required. The fundamental difference is that figures for a representative or "statistical" dwelling unit are used rather than figures for a specific dwelling unit. Recall that a "statistical" dwelling unit is one in which the dimensions and characteristics are based on averages computed from an actual sample of houses in a particular building type/age category.

The other major difference in input concerns the values for key factors, such as occupancy status and substrate condition, which take on a value of 1 or 0 when making contract cost estimates. When making policy estimates however, the program informs the user that percentages are required for these factors. This information should also be based on an actual sample of houses. If this information is not available, the percentages used as input could be based on previous studies in combination with expert judgement.

A table like Table 2.3 should prove useful in developing the input values of the key factors for each "statistical" dwelling unit. Table 2.3 shows the number of dwelling units in each type/age category. Table 2.3 is useful because it conveniently divides up the stock of housing into well defined categories. Information from the survey, especially the sample floor plan (Diagram 2.2), may then be used to calculate the value of specific key factors for each of the dwelling units.

Once the appropriate categories have been established, statistical methods of sampling may be used to insure that the values of the key factors for the "statistical" dwelling unit are representative of the population (i.e., the type/age category). (Should the LBP program office be recording the dwelling unit statistics on an automatic data processing (ADP) system, it would not be necessary to rely on statistical methods sampling since averages could be easily tabulated by the ADP system.) For example, if the survey revealed that 750 Pre 40 single family attached dwelling units would require deleading, it would not be necessary to calculate the values of the key factors for all 750 dwelling units and average them to get their values in the "statistical" dwelling unit. In most cases a random sample of 30 dwelling units should be enough to estimate a representative value of each key factor for the "statistical" dwelling unit.

If prior information on the standard deviation of each key factor for the population (type/age category) is available, a specific value of the sample size can be established. This value may be either larger or smaller than 30 and may vary among the key factors.¹ Should the

¹ For a thorough discussion see Mary Natrella, Experimental Statistics, National Bureau of Standards, Handbook 91, August 1963.

TABLE 2.3

NUMBER OF DWELLING UNITS BY TYPE/AGE CATEGORY

Dwelling Unit Type	Dwelling Unit Age		
	Pre 1940	1940- 1960	Post 1960

Multifamily High Rise			
Single Family Attached			
Single Family Detached One Story			
Single Family Detached Two or More Stories			

total number of dwelling units in a category be small, it is possible to base the average on all available data rather than just a randomly selected subset. (Note, if the number of dwelling units to be done is quite small, it might be better to use the contract cost estimation routine. This approach would be superior in that it would provide not only an estimate but the contract assignment as well.)

A table of random numbers may then be used to select the random sample. For example, you may choose to write down the first 50 three digit random numbers which occur in the table. You should then go through and rule out all those over 750 since you have only 750 dwelling units. Similarly you should also rule out any repetitions. In the event that you now have less than 30 random numbers you should continue where you left off in the table until you have generated the 30 needed to do the experiment. (An alternative way of selecting the random numbers is to go through the table as described above and choose only those numbers which are less than 750 and which have not already been recorded.) Assuming that you have a set of 30 random numbers, you are now in a position to sample from the set of dwelling unit data. This may be done by numbering each dwelling unit, in this case from 1 to 750, and identifying those whose number match one of the random numbers selected from the table of random numbers.

Once you have selected the random sample of dwelling units, the values of each of the (dwelling unit) key factors should be tabulated. The values of a particular key factor are then averaged and recorded in Table 2.4. Table 2.4 may then be used as a reference when inputting data on the "statistical" dwelling unit into the computer program.

Once the data have been input, the program continues as it did when making contract cost estimates by calculating per unit direct costs for each wall and trim technique. Painting costs are then computed. It is important to point out that instead of determining which technique is the least costly, the direct costs of all six different wall techniques and all four trim techniques are averaged. One cost for deleading walls and one cost for deleading trim results. The corresponding painting costs are then added to these average values to get total direct cost.

The final step is the computation of a markup ratio. The markup ratio is based on the values input on the statistical dwelling unit. Since a value for the total net square feet and linear feet in the contract is required in order to complete the markup estimating equation, a contract package size of three dwelling units is assumed. As soon as the markup ratio has been calculated it is multiplied by the total direct cost. The result is a total cost figure which includes an allowance for the contractor's overhead and profit. Once the cost information for this "statistical" dwelling unit has been printed, the user may either stop or perform another cost estimate for a different "statistical" dwelling unit (type/age category) based on the same wage and material data.

3. ACCESSING THE COMPUTER PROGRAM

3.1 Introduction to FACTS

The Federal Agencies' Computer Time-Sharing System (FACTS) is a library of programs aimed at facilitating the use of computers to solve construction related problems.¹ The FACTS library is part of the Remote Access Multi-User System (RAMUS), a nationwide interactive time-sharing computer and telecommunications network developed and operated by the General Services Administration (GSA). The RAMUS and FACTS systems are available to all Federal agencies and their authorized contractors. Before we proceed with a discussion of FACTS, it is important to outline how FACTS and RAMUS are related. RAMUS consists of four basic parts:

1. An executive system that acts as a master control center;
2. Permanent files that contain a number of standard programs and subroutines available for use by all subscribers;
3. User files that contain user-developed programs and serve as a temporary storage area for data to be used by the computer in solving specific problems;
4. A processing section that makes the actual calculations.

FACTS consists of two basic parts:

1. a library of engineering programs; and
2. an executive system that permits the user to access those library programs through RAMUS.

The advantage that FACTS offers over the basic RAMUS system is that it greatly facilitates the use of RAMUS by persons without computer experience. This is because the FACTS library programs have been written in such a way that the user is given step-by-step instructions on their use in the course of using them.

The FACTS executive system also permits the user to establish a user file. The user file will contain a program which is an exact copy of the computer program stored in the FACTS library. THE USER FILE MAY THEN BE REFERENCED DIRECTLY TO PROVIDE THE DESIRED COST ESTIMATES.

¹ For a detailed description of FACTS, see Users' Manual for the Federal Agencies' Computer Time-Sharing System, National Research Council, Building Research Advisory Board, Federal Construction Council, Technical Report 68, 1976.

In the next section we shall see how the program may be run once a user file has been established. However, before the computer program can be referenced and a user file established, the agency (or authorized contractor) must subscribe to the RAMUS service. Any agency or authorized contractor wishing to subscribe to the RAMUS service should initiate the administrative procedure by writing to:

Agency Services Coordination Division
ADTS, GSA
1776 Peachtree Street, NW
Atlanta, GA 30309

This letter should include the following information:

1. The date the agency wishes to begin RAMUS service;
2. The number and type of terminals which will be used;
3. The average number of hours per day of terminal connect time;
4. The estimated program storage requirements;
5. The name, address, and telephone number of the agency, the person to be contacted for information pertaining to RAMUS usage; and
6. The billing address and appropriate fund citation.

Item number 2 in the list above requests information about the type of office terminal to be used. In order to use RAMUS, the terminal should be either the Automatic Send/Receive Model 33 or 35 Teletypewriter, or any fully compatible equipment. The office terminal communicates with RAMUS by means of a telephone (voice grade) circuit; either FTS, WATS, or leased lines may be used. Once the user has received an identification code and password, he enters the FACTS library via RAMUS. (This procedure is analogous to checking a book out of a library and using the information in the book to solve a particular problem.)

3.2 Running the FACTS Program

Throughout this section it is assumed that the user has already established a user file in which a copy of the FACTS program is stored.¹ Once the user has signed onto the system, the terminal should respond with an output similar to that printed below.²

¹ Details of how the user enters the FACTS library of programs, retrieves the lead paint cost estimation procedure, and establishes a copy in the user file are given in Appendix B.

² Underlining indicates a user input.

```
GSA 440 TIME-SHARING SYSTEM 1
ON AT 10:16 PB:04 TTY:60
08/14/78
USER ID--
PASSWORD?
TYPE OLD OR NEW:  O  L  D
OLD:  K  A  H  0  0
READY
  R  U  N  B  I  G
```

Recall that at the end of each statement, e.g., OLD, you must press the nonprinting carriage return character. This tells the computer to proceed. Note that the program name, KAH00, refers to the name of the program being stored in your user file. When you establish your user file (see Appendix B) you will be asked to provide a name for the program which you wish to store. KAH00 was the program name selected in this case.

As soon as you enter RUNBIG after the computer has printed READY the program will begin requesting input information. Suppose that Table 3.1 corresponds to the input data we have collected on wages and material prices. The computer printout would then look like that presented immediately after Table 3.2. Note very carefully that 1) wages and material prices are entered one at a time after each question mark, ?, and 2) dollar signs are not used (i.e., 8.50 and not \$8.50).

After the last material price data has been entered, the computer will ask if program or contract cost estimates are desired. The printout shown above indicates that contract cost estimates are desired. The program then asks the user how many dwelling units are in the "preliminary" contract. Recall that no more than 10 dwelling units can be input at any one time. (In addition, the "preliminary" contract should contain dwelling units which are geographically close together.) The program then asks the user to check the input data for errors. If no errors have been made, the program begins requesting input information on dwelling unit number 1. Table 3.2 summarizes the relevant input data for dwelling unit number 1.

Once all data on dwelling unit number 1 has been entered, the computer will request the user to check over the input data in case any errors have been made in entering the data. The output from the terminal in this case is shown immediately after Table 3.2.

If no errors were made while the data on dwelling unit number 1 were being input, the program will proceed to the next dwelling unit. This process continues until the data on all 10 dwelling units have been input (see Diagram 2.1). The program then groups the dwelling units into contract packages in such a way that the sum of the bid prices is minimized.

3.3 How to Interpret the Computer Output

In the previous section we saw how the data on a specific dwelling unit as well as wages and material prices were entered into the computer program. Assuming once again that we wish contract cost estimates on the 10 dwelling units discussed in the previous section and that data on each dwelling unit has been input into the computer, an output similar to that which follows will result.

READY
BYE
OFF AT 11:04

You will notice that four contracts resulted in this case. Contract number 1 has four dwelling units in it (dwelling units 8, 4, 9 and 6); contracts 2 through 4 have two dwelling units each.¹

In each contract the dwelling unit number and address is given on the top line. On the second and third lines the least cost wall technique and least cost trim technique are given. The direct cost of deleading the dwelling unit is given on the fourth line. For example, dwelling unit number 8 is located on 116 Main Street, the least-cost wall technique is cementitious coating, the least-cost trim (paint removal) technique is the electric heat gun, and the total direct cost is approximately \$480. After this information has been presented for each dwelling unit the contract price (expected bid price) and the expected markup ratio are printed out in the lower right hand corner. For example, in contract package number 1, the expected bid price is approximately \$3125 with a markup ratio of 1.16 (that is, a 16 percent markup for overhead and profit).

The output shown above indicates that all 10 dwelling units can be delead for approximately \$9300, including contractor markup. The nature of the information input on each dwelling unit and the output from the computer program should greatly facilitate budgeting, the preparation of specifications, and the establishment of which dwelling units should be in each contract package.

¹ All of the input information which is associated with the output presented above is given in Appendix C.1. Appendix C.1 should also prove useful to those readers interested in examining a complete computer run prior to making any contract cost estimates on their own. (Appendix C.2 is intended to serve as a model for those readers interested in performing baseline program cost estimates.)

4. SUMMARY

This report describes a computerized cost estimation procedure based on the results of the Experimental Hazard Elimination Program (EHEP). The data requirements associated with the EHEP computerized cost estimation procedure are discussed as are means through which these data can be obtained. A discussion of the Federal Agencies' Computer Time-Sharing System (FACTS), where the EHEP procedure is in permanent storage, was also presented. Guidelines for how to reference the procedure via FACTS and create a "copy" in a user file were presented as were examples of actual computer runs. A sample output providing contract package assignments and cost estimates for 10 dwelling units was presented. This example was used to illustrate how the output identified not only the least costly technique for deleading walls and trim but facilitated the budgeting, specifications writing, and contract packaging, tasks in the typical local or regional lead paint abatement program office.

APPENDIX A: DESCRIPTION OF ABATEMENT TECHNIQUES

This appendix is intended to supply background information on three basic methods of lead-based paint (LBP) abatement. The three abatement methods are subdivided into individual abatement techniques. The abatement techniques are then described individually in some detail, with regard to their composition, method of application, and/or any special skill or material/equipment requirements.

Since the body of this appendix is formed of excerpts from publications in which these abatement techniques are described in greater detail the interested reader is referred to the two reports by Boone et. al.¹

A.1 BARRIER MATERIALS

The complete stripping of LBP from surfaces as well as the removal and replacement of building components which are coated with LBP are defined here as LBP elimination methods. The effectiveness of such methods is essentially total. However, the application of these methods to large wall surfaces appears to be both impractical and prohibitively expensive. The application of materials, which are intended to act as barriers, is frequently the most reasonable approach to the abatement of LBP on planar surfaces. The effectiveness of barrier materials is therefore a function of the degree to which they prevent access to the existing LBP which they cover. The material's strength, durability and permeance are the primary characteristics that establish its effectiveness in LBP abatement.

A.1.1 GYP SUM WALLBOARD

Gypsum wallboard is a product which is composed of a thick layer of gypsum to which paper or other materials are bonded to provide a finished or finishable surface. It is intended for use on walls, ceilings, or partitions, and can be applied directly to existing surfaces or to wood or metal furring strips.

It can be applied directly to existing walls with adhesives and nails. The installed wallboard is prepared for painting by finishing the joints between the sheets with joint tape and compound. Nail heads are then covered with compound and both areas are sanded to a smooth finish.

¹ Thomas H. Boone, Harvey W. Berger, A. Philip Cramp, Herbert A. Jackson The Demonstration of Experimental Lead Paint Hazard Abatement Methods in Washington, D.C., National Bureau of Standards, NBSIR 75-761, June 1975, and Thomas H. Boone, Harvey W. Berger, A. Philip Cramp, Herbert A. Jackson, The Demonstration of Experimental Lead Paint Hazard Abatement Methods in Atlanta, Georgia, National Bureau of Standards, NBSIR 75-974, December 1975.

A.1.2 PLYWOOD PANELING

This product is a 5/32 inch (4 mm) thick lauan mahogany plywood panel which has been treated with a multiple coat catalyzed varnish finish. The material is supplied in 4 x 8 feet panels (1.2 x 2.4 m) and is applied to existing walls with either fasteners or an adhesive. Pre-formed strips are used to cover vertical butted seams and as a molding at the ceiling line. Wood baseboards are applied over the paneling along the floor line.

A.1.3 CEMENTITIOUS COATING

The cementitious coating consists of portland cement, sand, and acrylic resin to which water is added to make a slurry. It can be tinted to desired colors by the addition of pigments recommended by the manufacturer.

The cementitious coating is viscous and has a rough texture. It can be applied by brush or roller or any other equipment designed to apply viscous filled coatings.

The surface must be clean and free from loose particles. Glossy surfaces must be roughened with an abrasive, and chalky surfaces sealed with a sealer to ensure good adhesion. The applied coating has a final thickness of about 1/16-inch (about 1.6 mm).

A.1.4 GYPSUM VENEER PLASTER

This product is a component pre-packaged material which becomes plastic when mixed with water so that it can be trowel applied to form a highly polished finish or can be worked to achieve a textured finish. It may be applied to solid plaster walls which have first been treated with a vinyl polymer bonding compound to improve adhesion to the existing painted surfaces. The finished thickness of the plaster is approximately 1/8-inch (3.2 mm) thick. Skilled workmen are required for the satisfactory application of this product.

A.1.5 VINYL-COATED FABRIC

Vinyl-coated fabric is basically similar to wallpaper or vinyl-clad paper. Its strength and durability exceed that of the other two materials because of its combination of vinyl surface and textile fabric backing.

Vinyl-coated fabric may be installed on any wall surface that is free of dirt, grease, oil and moisture. The method used for hanging vinyl-coated fabric is the same as used for hanging wallpaper. The adhesive used depends upon the weight of the vinyl-coated fabric. These fabrics normally resist soiling and staining even by objects such as crayon, lipstick, or ink. A mild detergent and a sponge usually will remove most soils and stains. These fabrics conform to the bends and contours

of most surfaces and are installed readily by workmen who are familiar with wallpaper installation using ordinary hand tools and equipment.

A.1.6 CEMENT-COATED FIBERGLASS

This product consists of glass fabric impregnated with portland cement. It is applied to walls in the same manner as wallpaper, with a waterbase adhesive. As the portland cement absorbs moisture from the environment it hardens and becomes a fairly rigid and penetration-resistant material. A protective coating should be applied if the material is to be used in wet areas.

A clean substrate in good repair is necessary for adequate adhesion. The covering will, however, bridge minor voids and mask minor substrate imperfections.

The following barrier materials were used in Phase I of EHEP but were dropped from consideration during the Phase II deleading operations because of excess cost, logistical problems or similarities with other techniques that were used in Phase I.

A.1.7 MELAMINE-COATED HARDBOARD

This product is a 1/4-inch (6.4 mm) thick tempered hardboard to which a 1-1/2 mil (.038 mm) thick melamine film has been laminated to provide a serviceable, decorative finish. The material is supplied in 4 x 8 feet panels (1.2 x 2.4 m) and is applied to existing walls with fasteners or an adhesive. Pre-formed strips are used to cover vertical butted seams and as a molding at the ceiling line. Baseboards are applied over the paneling at the floor.

A.1.8 AGGREGATE FILLED PAINT

This coating is a latex based product which contains sand or other mineral aggregate which provides a thick finish comparable in texture to sand finish plaster.

Filled paint is viscous. The product used was formulated for application by airless spray equipment, but it and most other formulations can be applied using a brush or roller. It requires no mixing or thinning and it can be applied successfully to any surface which is free of dirt, oil or grease. Primers are not required for use on previously painted surfaces and thicknesses as high as 20 mils (0.02 inch or 0.05 cm) can be obtained with one coat. The finish texture, ranging from smooth to coarse, depends upon the aggregate quantity and particle size.

A.1.9 GYPSUM PLASTER WITH METAL LATH

Gypsum plaster is applied to a metal lath which serves as a support for the plaster and a means of adhesion to the surface being treated. The lath is a netting of 20 gauge galvanized steel which is fastened to a surface with nails, staples or screws.

The plaster is usually applied in two stages resulting in a final thickness of 1/2-inch (1.3 cm). In the first application, wood fiber is added to the gypsum plaster to improve its working characteristics by making it easier to apply and to increase its adhesion to the metal lath. This first coat is applied by trowel to a uniform thickness of about 3/8-inch (1 cm). The plaster sets up (hardens) rapidly and must be applied quickly. Highly calcined gypsum plaster is used for the second or top-coat. This plaster contains a retarder which delays hardening so that the desired finish (smooth or textured) can be achieved. The final coat is about 1/8-inch (0.3 cm) thick. The finished dried surface is usually painted.

The application of plaster to lath should be done by skilled workmen. The temperature of the work area and surface should be above 50°F and adequate ventilation (for proper drying of the plaster) should be provided.

A.1.10 GYPHUM IMPREGNATED JUTE FABRIC

This wall covering product consists of jute fabric which is impregnated with uncrystallized gypsum (hydrated calcium sulfate). It is applied to walls in the same manner as wallpaper, with a water base adhesive which is recommended by the manufacturer of the fabric. As the gypsum absorbs moisture from the air, it hydrates, hardens and becomes a fairly rigid and penetration-resistant material. A protective coating can be applied if the material is to be used in wet areas.

A clean substrate in good repair is necessary for adequate adhesion. The covering will, however, bridge minor voids and mask minor substrate imperfections.

A.1.11 PLYWOOD ON FLOORS

Plywood may be used to cover-up lead painted exterior wood decks on porches. Warped and rotted boards are replaced with new or sound ones and a 15 lb. (6.8 kg) roofing felt is put down as an underlayment before installing the plywood.

Four by 8 feet (1.2 x 2.4 m) sheets of 3/8-inch (9.5 mm) A-B grade, exterior or marine plywood are used. All edges are treated with wood preservative and the sheets are nailed or screwed to the existing deck with their A grade surface up. All exposed edges are covered with wood trim and the new surface is painted with one coat of primer and two coats of exterior paint.

Skilled workmen are required to install plywood on existing porch decks with satisfactory workmanship. Although the job can be done with hand tools, it can be accomplished much more easily with ordinary power tools such as electric drills and saws.

A.2 PAINT REMOVAL METHODS

The safety of workmen and dwelling occupants is a primary consideration in the implementation of paint removal methods. Procedures should be taken to avoid the inhalation or absorption of lead fumes or dust. In addition, attention should be given to the potential fire hazard associated with the use of open flame paint removal techniques.

A.2.1 INFRA-RED HEATING DEVICE

The infra-red heating device used in Phase II of EHEP consists of a propane burner whose flame is recessed in a metal reflector covered with a metal grid. When the flame is lit, the grid is heated. The device is held near the surface that is to be stripped. The heat radiating from the grid causes the paint to soften, swell and/or blister so that it can be removed easily from its substrate with metal scrapers.

This device is somewhat less hazardous than a propane torch because the open flame is recessed. Completely portable, it uses one pound disposable propane cylinders or a 25 pound refillable propane tank. The process of heating and scraping can be carried out by a single workman.

A.2.2 SOLVENT-BASED PAINT REMOVER

A number of "industrial grade" paint removers may be used to remove LBP from windows, doors and other wood trim components. These viscous liquids are applied to both horizontal and vertical surfaces by brush, allowed to react with the lead paint coatings and then removed along with the softened paint using various metal scrapers.

Paint removers are extremely variable in their ability to penetrate and react with multiple layers of dried paint. The effectiveness of the remover depends not only on its own composition but also on the nature of the multi-layered coating to which it is applied. Most removers will react with only 2 to 4 layers of paint at a time. In such cases where more than that number of layers of paint is present, the remover-paint agglomeration must be removed and fresh remover applied as often as necessary to achieve complete removal.

Generally, the reaction time for paint removers is about one-half hour. The remover-paint waste, which is scraped from the treated surfaces, is collected on polyethylene drop clothes and discarded. Prior to light sanding and repainting, the surface is wiped with a water-saturated rag in order to remove any residue of remover-paint mixture.

Proper precautions regarding open flames, adequate ventilation and avoidance of contact with skin is necessary to assure the safe use of this class of products.

A.2.3 ELECTRICAL HEAT GUN

Another technique for removing paint from doors, windows and other wood surfaces by means of heat generation is a portable flameless electric hot air blowing device. It is quite effective in removing paint from wood substrates as demonstrated in laboratory tests; it also presents an apparent low risk of fire and injury to operators or bystanders.

A commercially manufactured device consists essentially of an air blower attached to a reinforced flexible plastic hose, with a cylindrical electric heater at the outlet. The heater is heavily insulated, so that it can be hand held while in operation. This apparatus is mounted on a stand which makes it quite mobile. It is capable of producing a strong stream of hot air at temperatures of between 350° and 1000°F (175° and 540°C). The working end of the device is very lightweight and a single workman can perform the continuous operations of heating the paint to its softening point and scraping it off with metal tools. Electrical circuits or portable generators supplying 20 ampere currents at 110-120 volts are required for operation of the hot air blower.

A.2.4 HAND SCRAPING

Simple hand tools such as paint scrapers and putty knives may be used to remove loose and flaking paint. Electrical sanders may then be used to achieve the complete removal of paint which are adhered too tightly to those surfaces for hand scraping.

The following paint removal methods were used in Phase I of EHEP but were dropped from consideration during the Phase II deleading operations because of excess cost, potential fire hazards, logistical problems, or similarities with other techniques that were used in Phase I.

A.2.5 PROPANE TORCH

The open flame produced by a propane torch can be used to heat paint directly to the softening point so that it can be scraped off with metal tools. The process is easily carried out by a single workman using a one pound propane bottle.

Until recently, the use of propane torches had been quite widespread for this purpose. They are now falling into disfavor, however, due to the extreme fire hazard of an open flame (especially in occupied and furnished dwellings) and the health hazard of over-heating paints to the point of vaporization of the pigments.

A.2.6 DIP TANK METHOD

Commercial furniture stripping plants have facilities for removing old paint and varnish by totally immersing the object of interest in large tanks containing heated alkaline solvents in an aqueous medium.

Doors may be stripped by this process, requiring two to three hours of treatment during which time they are alternately soaked and scrubbed with heavy bristle brushes. The total stripping time is dependent on the type of paint, the number of paint layers and the temperature and strength of the solvent bath. Doors can be stripped with hinges and other hardware still attached. After the paint is completely removed the doors are washed with water, air dried, planed, and then returned to the dwelling unit where they are reinstalled and repainted.

A.3 REPLACEMENT OF COMPONENTS

Removal of doors, door frames, windows and frames, and other trim components and replacement with new materials is an accepted technique of LBP abatement. Replacement is used primarily when building components have deteriorated or are damaged beyond the point of serviceability. This method, in addition to restoring the building component to serviceability, also provides an opportunity to upgrade the quality of the dwelling unit significantly.

Carpentry skills are required for rehanging, fitting and remounting hardware. Custom carpentry may be required for replacing wooden sash windows and frames in some dwelling units.

APPENDIX B: REFERENCING THE FACTS LIBRARY

The purpose of this appendix is to demonstrate how the user can reference the cost estimation procedure via the FACTS library of programs. The appendix is organized in such a way that the user can become familiar enough with the FACTS library to set up a user file. The user file, which is established by following the steps presented in this appendix, contains an exact copy of the cost estimation program. Once a user file has been established it is no longer necessary to repeat each step outlined in this appendix. In particular, in order to obtain the desired cost estimates it is only necessary to "call up" and "run" the program stored in the user file.

Throughout the following discussion it will be assumed that the user has already established his subscription to the RAMUS service. In particular, it is assumed that the user has (1) the telephone number through which the system can be referenced, (2) a user ID and (3) a password.

Before the FACTS library can be referenced, the user must first call RAMUS. Once connected with RAMUS, the computer will request a user ID, a secret password, and the type and name of the program to be used.¹ A sample of the type of information requested is shown below. Note, the computer will print over the password so that it can not be deciphered and used by someone else.

```
GSA 440 TIME-SHARING SYSTEM 1 ON AT - 11:23 PB:04 TTY:60
```

```
12/12/78
```

```
USER ID--  _ _ _ _ _
```

```
PASSWORD?  _ _ _ _ _
```

```
TYPE OLD OR NEW: OLD: FACTS***
```

¹ At the end of each statement, e.g., B310, you must press the non-printing carriage return character. This tells the computer to proceed. If you make a mistake, e.g., typing B315 instead of B310, you can correct by using the character +. To change B315 to B310, you would type + once and then 0. The line would then look like B315+0. In the event that you do not have enough space to make corrections using the character +, you can press the escape key (ESC). This action will cause the input for that line in the computer program to be requested a second time. If you get in a real bind, hit the BREAK character. This disconnects you from RAMUS.

The computer is now ready to run FACTS. In response to the computer's READY signal, please type RUNBIG. The computer will then ask what level of prompting you wish; in response to the ***, enter HE as in the sample below.

READY
RUNBIG

FACTS RESPONDING. INDICATE LEVEL OF PROMPTING AT ***, PROMPT
ENTER TO GET

AB ABBREVIATED PROMPTING
FL FULL PROMPTING
HE FULL PROMPTING + SYSTEM EXPLANATION

***? HE

The computer will then print the following details on FACTS.

FACTS CONSISTS OF AN EXECUTIVE SYSTEM AND A LIBRARY OF FULLY TESTED
ENGINEERING AND SCIENTIFIC COMPUTER PROGRAMS.

THE FACTS EXECUTIVE SYSTEM ALLOWS THE USER TO FULLY UTILIZE THE FACTS
LIBRARY OF ENGINEERING AND SCIENTIFIC COMPUTER PROGRAMS BY (1) PROVIDING
LIBRARY VISIBILITY, (2) CONSTRUCTING COMMANDS PROGRAMS FOR THE USER WHICH
TAKE CARE OF ALL SYSTEM DETAILS THAT ARE NECESSARY FOR SETTING UP AND
RUNNING FACTS PROGRAMS AND (3) PROVIDING USER LIBRARY MANAGEMENT. THESE
FUNCTIONS ARE ACCOMPLISHED WITHIN SUBLEVELS OF THE EXECUTIVE SYSTEM.
SUBLEVEL STATUS IS ACHIEVED THROUGH THE USE OF COMMANDS GIVEN TO THE
COMPUTER IN RESPONSE TO THE ***, PROMPT PRINTED IN THE EXECUTIVE SYSTEM
COMMAND LEVEL. THE THREE PRINCIPAL FUNCTIONS OF THE FACTS EXECUTIVE
SYSTEM ARE AS FOLLOWS:

(1) LIBRARY VISIBILITY IS ACHIEVED THROUGH THE LIST AND BRIEF SUBLEVELS

/LIST SUBLEVEL/-PROVIDES A LIST OF COMPUTER PROGRAMS CURRENTLY AVAILABLE
IN THE FACTS LIBRARY. THE FACTS LIBRARY, WHICH IS CONSTANTLY EXPANDING,
IS DIVIDED INTO SUBAREAS THAT ARE IDENTIFIED BY EITHER A SINGLE ALPHABET
LETTER OR BY A LETTER AND A NUMBER. A LIST OF THE SUBAREAS AND THE
NUMBER OF FACTS PROGRAMS IN EACH SUBAREA IS AVAILABLE AS AN OPTION
WITHIN THE LIST SUBLEVELS OF THE EXECUTIVE SYSTEM.

/BRIEF SUBLEVEL/-PROVIDES A SHORT DESCRIPTION OF THE CAPABILITIES AND
DATA REQUIREMENTS FOR EACH PROGRAM IN THE FACTS LIBRARY.

(2) CONSTRUCTION OF COMMANDS PROGRAMS IS ACHIEVED THROUGH THE CONSTRUCT
SUBLEVEL.

/CONSTRUCT SUBLEVEL/-FOR EACH FACTS LIBRARY PROGRAM THAT THE USER WANTS TO RUN, THE COMPUTER CREATES A SMALL COMMANDS PROGRAM TO HANDLE ALL THE DETAILS REQUIRED TO MAKE THE PROGRAM OPERATIONAL. THIS SMALL PROGRAM IS STORED IN THE USERS OWN LIBRARY BY THE COMPUTER AND ITS NAME RECORDED IN A DIRECTORY FILE THAT THE COMPUTER GENERATES FOR THE USER THE FIRST TIME IT CREATES A COMMANDS PROGRAM FOR HIM. EACH TIME THE USER CREATES ANOTHER COMMANDS PROGRAM IT IS ALSO STORED IN HIS LIBRARY AND ITS NAME IS ADDED TO HIS DIRECTORY FILE. THUS, THE USERS DIRECTORY FILE CONTAINS A CURRENT LIST OF THE COMMANDS PROGRAMS THAT ARE IN HIS LIBRARY. COMMANDS PROGRAMS ARE CREATED BY THE FACTS EXECUTIVE SYSTEM BUT THEY ARE RUN UNDER RAMUS IN THE SAME MANNER AS ANY OTHER COMPUTER PROGRAM ON THE RAMUS SYSTEM. A COMMANDS PROGRAM, ONCE GENERATED, CAN BE USED OVER AND OVER AGAIN WITHOUT RETURNING TO THE FACTS EXECUTIVE SYSTEM.

(3)MANAGEMENT OF THE USERS LIBRARY OF COMMANDS PROGRAMS IS HANDLED THROUGH THE DELETE, DIRECTORY AND MESSAGE SUBLEVELS.

/DELETE SUBLEVEL/-PROVIDES THE MECHANISM FOR LISTING THE CONTENT OF THE USERS DIRECTORY FILE(S) AND FOR DELETING COMMANDS PROGRAMS FROM HIS LIBRARY. THE NAMES OF DELETED COMMANDS PROGRAMS ARE REMOVED FROM THE USERS DIRECTORY FILE. THUS, THE DIRECTORY IS ALWAYS CURRENT.

/DIRECTORY SUBLEVEL/-ALLOWS THE USER TO LIST THE CONTENT OF HIS DIRECTORY FILE(S).

/MESSAGE SUBLEVEL/-ALLOWS THE USER TO MAKE COMMENTS ON FACTS DURING THE ACTUAL USE OF THE SYSTEM. MESSAGES ARE REVIEWED AT FREQUENT INTERVALS AND THE USER IS NORMALLY CONTACTED IF ADDITIONAL INFORMATION IS REQUIRED.

NOTE: COMMANDS AND RESPONSES SHOULD BE ENTERED ONLY IN RESPONSE TO PROMPTS: OTHERWISE IT CONFUSES THE COMPUTER. ALSO, THINK BEFORE YOU RESPOND TO A COMPUTER PROMPT, A LITTLE THOUGHT WILL PAY-OFF.

THE FACTS LIBRARY CONSISTS OF A NUMBER OF FULLY TESTED ENGINEERING AND SCIENTIFIC COMPUTER PROGRAMS. THESE PROGRAMS ARE REALLY SUBROUTINES AND EACH CONTAINS A PREAMBLE WHICH DEFINES THE PURPOSE OF THE PROGRAM, THE DATA REQUIRED TO MAKE IT OPERATIONAL AND OTHER INFORMATION NECESSARY FOR ITS EFFICIENT OPERATION. SINCE THESE PROGRAMS ARE SUBROUTINES, THEY MAY BE LINKED TOGETHER FOR SOLVING EXTREMELY COMPLEX PROBLEMS WHERE A MULTIPLICITY OF OPERATIONS ARE REQUIRED. THE FACTS EXECUTIVE SYSTEM CAN READ AND INTERPRET THE CONTENT OF THE PREAMBLE OF FACTS PROGRAMS AND FROM THIS ANALYSIS, CREATE A COMMANDS PROGRAM CONTAINING THE ELEMENTS THAT ARE NECESSARY FOR MAKING THE FACTS SUBROUTINE FULLY OPERATIONAL.

YOU ARE NOW AT COMMAND LEVEL (PROMPT SYMBOL***).
 ENTER NEXT FACTS COMMAND AT ***? PROMPT.

***? RA

<<<

ALL PROGRAMS, INCLUDING THE FACTS EXECUTIVE SYSTEM, ARE RUN UNDER THE CONTROL OF RAMUS (REMOTE ACCESS MULTI-USER SYSTEM). IN ORDER TO RUN A COMMANDS PROGRAM DEVELOPED WITHIN FACTS, THE USER MUST EXIT TO RAMUS. THIS CAN BE DONE AT ANY TIME BY TYPING AN S AND THEN HITTING A CARRIAGE RETURN OR WHEN AT COMMAND LEVEL THE USER MAY TYPE STOP. AT RAMUS LEVEL THE USER MAY RUN ANY PROGRAM BY TYPING "RUN OPTION: PROGRAM NAME" FOR EXAMPLE, IF THE USER WANTED TO RUN A COMMANDS PROGRAM NAMED RLR01 AND ITS RUN OPTION IS RUN, THE USER WOULD TYPE RUN: RLR01 AND THEN HIT A CARRIAGE RETURN. (FOR GREATER DETAIL OF THE RAMUS SYSTEM AND ITS OPTIONS, THE USER MUST OBTAIN A COPY OF THE OPERATING SYSTEM MANUAL THROUGH GSA).

YOU ARE NOW AT COMMAND LEVEL (PROMPT SYMBOL***).
 ENTER NEXT FACTS COMMAND AT ***? PROMPT.

STOP	STOP		RETURNS USER TO RAMUS SYSTEM

In response to ***, please type LI; this will get you to the LIST level of FACTS. When the computer prints ###?, please type *; this will tell the computer to list all the functional codes, the number of programs in each area, and a description of the functional code. Typing LI in response to the first question, and * in response to the second will cause the following output to be printed.

***? LI

YOU ARE NOW AT LIST LEVEL (PROMPT SYMBOL ###).

ENTER ONE FUNCTIONAL AREA CODE (E.G. J) IN RESPONSE TO EACH PROMPT.

ENTER AN * FOR LIST OF CODES. ENTER WORD END TO RETURN TO COMMAND LEVEL.

###?*

<u>FUNCTIONAL</u> <u>AREA CODE</u>	<u>PROGRAMS</u> <u>IN AREA</u>	<u>DESCRIPTION</u>
E	1	ELECTRICAL
H ₁	8	HYDRAULICS-SPILLWAYS
H ₂	11	HYDRAULICS-OUTLET WORKS
H ₃	2	HYDRAULICS-GATES & VALVES
H ₆	23	HYDRAULICS-OPEN CHANNELS
H ₇	5	HYDRAULICS-SPECIAL PROBLEMS
I	4	SOILS
J	3	ECONOMICS
L	2	MECHANICAL
M	1	MATHEMATICAL
U	1	GEODESORY & SURVEYING
X	21	STRUCTURAL
Z	1	OTHER

After the computer has printed information on the functional codes, it will ask the user if a listing of individual programs is desired. Since the program on deleading costs is stored in the functional area code J, the user should enter J in response to ###. The listing will then identify J0003 as the desired program. (Note, as of the date of the printing of this publication, the computerized cost estimation program had not been placed in the FACTS library. Thus, the listing of all programs in the J, economic, functional area code is necessary to determine if J0003 is the correct FACTS program number.) An output similar to that which follows would then be printed.

The user should then type END and BR in response to the prompting, ***, question from the computer so that a brief of program J0003 can be obtained (see below).

***? BR

YOU ARE NOW AT BRIEF LEVEL (PROMPT SYMBOL \$\$\$).
ENTER ONE PROGRAM NAME (E.G. H2Ø1Ø) IN RESPONSE TO EACH PROMPT.
TYPE WORK END TO RETURN TO COMMAND LEVEL.
\$\$\$? JØØØ3

I. DESCRIPTION

JØØØ3 WILL ANALYZE THE COSTS OF THE ALTERNATIVE METHODS FOR ELIMINATING THE LEAD PAINT HAZARD FROM A DWELLING UNIT. THE PROGRAM PERMITS THE USER TO INPUT SPECIFIC INFORMATION ON ANTICIPATED CONTRACT PACKAGES OF DWELLING UNITS. THE LEAST-COST COMBINATION OF ABATEMENT TECHNIQUES FOR EACH DWELLING UNIT IS IDENTIFIED. DWELLING UNITS ARE GROUPED TOGETHER INTO CONTRACT PACKAGES SO THAT THE SUM OF THE EXPECTED BID PRICES IS MINIMIZED. THE EXPECTED BID PRICE FOR EACH CONTRACT IS GIVEN. EXPECTED CONTRACT COSTS FOR EACH DWELLING UNIT ARE ALSO GIVEN.

II. LIMITATIONS

JØØØ3 WILL HANDLE ANTICIPATED CONTRACT PACKAGES OF UP TO 1Ø DWELLING UNITS. DATA FOR EACH DWELLING UNIT IS ENTERED IN RESPONSE TO QUESTIONS AT RUN TIME.

III. DATA

TWO TYPES OF DATA ARE INPUT, CONTRACT SPECIFIC DATA AND DWELLING UNIT SPECIFIC DATA. INPUT DATA FOR EACH ANTICIPATED CONTRACT CONSIST OF THE FOLLOWING:

A. CONTRACT SPECIFIC DATA

WAGE	AVERAGE HOURLY WAGE RATE
CARPENTER	"
PAINTER	"
PLASTERER	"
PAPER HANGER	"
APPRENTICE CARPENTER	"
LABORER	"

MATERIAL

GYPSUM WALLBOARD	PRICE PER 4' x 8' SHEET
PLYWOOD PANELING	"
VINYL-COATED FABRIC	PRICE PER SQUARE YARD
CEMENT-COATED FIBERGLASS	PRICE PER SQUARE YARD
FLAT LATEX WALL PAINT	PRICE PER GALLON
SEMI-GLOSS ENAMEL (OIL BASE)	PRICE PER GALLON

IF NEEDED:

UNFINISHED DOOR	PRICE FOR ONE, NEW
UNFINISHED DOOR FRAME	"
UNFINISHED WINDOW AND FRAME	PRICE FOR BOTH, NEW

B. DWELLING UNIT DATA

GROSS SQ. FT. OF WALL AREA	SQUARE FEET	
NET SQ. FT. OF WALL AREA	"	
LINEAR FT. OF DOORS AND FRAME	LINEAR FEET	
LINEAR FT. OF WINDOWS & FRAMES	"	
LINEAR FT. OF MISCELLANEOUS TRIM	"	
OCCUPANCY	PERCENT OCCUPIED	OR 1 IF OCCUPIED Ø IF UNOCCUPIED
WAINSCOTING	PERCENT OF WALL AREA	
SUBSTRATE CONDITION	PERCENT UNSOUND	OR 1 IF POOR Ø IF SATISFACTORY OR BETTER
PANTRY WORK	PERCENT NEEDING IT	OR 1 IF NEEDED Ø IF NOT
WALLPAPER ON WALLS	PERCENT HAVING > 2 LAYERS	1 IF 3 OR MORE LAYERS Ø IF NOT

IF NEEDED:

NUMBER OF DOORS TO REPLACE	NUMBER
NUMBER OF DOOR FRAMES TO REPLACE	"
NUMBER OF WINDOWS AND FRAMES TO REPLACE	"
ADDRESS	DU/AGE CATEGORY
XRF READINGS	AVERAGE OR SEPARATE OR ADDRESS AS SPECIFIED FOR EACH TRIM TYPE

FINISH
\$\$\$? END

The user has now identified the computerized cost estimation program and is now ready to construct a file to store a "duplicate" of the FACTS program. To do this, type END in response to \$\$\$, and then CO in response to the prompting, ***?, question. Study the following steps carefully. First, when the computer prints +++?, hit the nonprinting carriage return character. Second, type J0003 (if the FACTS program number for the computerized deleading program was different, please enter that number) when the computer prints +++?. Third, type FINIS.

Fourth, enter three letters (for example, your initials). The FACTS executive system then automatically establishes a directory file and assigns you a program name. You should record this information where you can easily refer to it. Fifth, type END. Sixth, type STOP. These six steps should generate an output similar to that which follows.

***? CO

YOU ARE NOW AT CONSTRUCT LEVEL (PROMPT SYMBOLS +++)
ENTER DIRECTORY FILE NAME? IF YOU DON'T HAVE ONE, HIT A CARRIAGE RETURN.
+++ ?

ENTER ONE PROGRAM NAME (E.G. H2Ø1Ø) IN RESPONSE TO
EACH PROMPT. AFTER ALL NAMES HAVE BEEN ENTERED, TYPE FINIS AFTER
SUBSEQUENT PROMPT.
+++ ? JØØØ3

+++ ? FINIS

ENTER 3 CHARACTERS (E.G. YOUR INITIALS) TO BE USED AS A PREFIX
IN NAMING YOUR NEW DIRECTORY FILE.

+++ ? KAH

THE FOLLOWING PROGRAMS ARE ADDED TO YOUR DIRECTORY FILE KAH1ØØ
(MON 12/12/78)

COMMANDS	PROGRAM NAME	FACTS	PROGRAM USED	RUN OPTION
	KAHØØ	JØØØ3		RUNBIG

THESE PROGRAMS WILL BE SAVED UNTIL YOU DELETE THEM. THEY CAN BE RUN AT
RAMUS LEVEL BY ENTERING RUN OPTION: COMMENTS PROGRAM NAME (E.G. RUNBIG:
SRHØØ).

*** ? STOP

The computer has now returned you to RAMUS. You may now run your program
by typing OLD: (your program name) and then RUNBIG after the computer
prints READY.

APPENDIX C: SAMPLE COMPUTER RUNS

The purpose of this appendix is to provide the reader with detailed examples of actual computer runs. The reader is encouraged to carefully study the computer runs included in this appendix since examples of both contract and program cost estimates are provided. Once the reader has studied the type and nature of the data inputs and outputs, it should be possible for both sections of the computer program to be run and interpreted with little or no difficulty.

C.1 Forecasting Abatement Costs for an Individual Dwelling Unit or Contract

A sample computer run for estimating the cost of deleading 10 dwelling units is provided in this section. This computer run is intended to illustrate 1) the type and nature of data inputs, 2) the way in which the computer output identifies the dwelling units in a contract package and estimates their deleading costs, 3) the way in which the computer output identifies the least cost abatement technique for each dwelling unit, and 4) the way in which the computer output identifies the expected bid price and markup ratio of the contract.

Recall that information on no more than 10 dwelling units can be input into the computer program at any one time. In addition, every effort should be made to group dwelling units so that they are geographically close when establishing the "preliminary" contract package. In the example presented in this section all 10 dwelling units are on the same block. Although this does not imply that only dwelling units which are in the same neighborhood should be grouped together, care should be exercised to insure that contractor transportation costs are held to a minimum.

C.2 Forecasting Abatement Costs for a Major Program

The purpose of this section is twofold. First, it is intended that this section illustrate the type and nature of data inputs and outputs associated with the use of the computer program for policy analysis. Second, a framework for estimating baseline program costs based on the results of the dwelling unit survey is established.

Part 2: Baseline Program Cost Estimate

In Section 2.4 a framework for determining baseline program cost estimates based on the results of the dwelling unit survey was developed. Based on the results of the computer run presented in Part 1, we can conclude that the costs of deleading the "statistical" Pre 40 Single Family Attached dwelling unit is approximately \$810. Now since the dwelling unit survey revealed that there were 750 dwelling units in this category (see Section 2.4), a baseline program cost estimate of approximately \$610,000 is indicated. Once the different types and ages of dwelling units in the region under study have been identified and the number of dwelling units in each category counted, a table similar to Table 2.3 can be constructed. Unlike Table 2.3 this table would include the baseline program cost estimate rather than the number of dwelling units in each category. Strategies for dealing with particular type/age categories based on program costs could then be developed.

13. Narrative								
Program will analyze the costs of the alternative methods for eliminating the lead paint hazard from a dwelling unit. It permits the user to input specific information on anticipated contract packages of dwelling units. The least-cost combination of abatement techniques for each dwelling unit is identified. Dwelling units are grouped together into contract packages so that the sum of the expected bid prices is minimized. The expected bid price for each contract and expected contract costs for each dwelling unit are given.

16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) This report describes a computerized procedure for estimating the cost of eliminating the lead-based paint hazard from buildings. This procedure is based on the results of an extensive field test program in which lead-based paint hazard abatement activities were carried out in approximately 200 dwelling units. The computerized cost estimation procedure which emerged is particularly useful because it takes into consideration both variations in the conditions of the dwelling unit as well as in the prices for labor and materials. As a result, it permits the least costly abatement technique to be identified under a wide variety of circumstances. In addition, when contract cost estimates are desired, the computer program groups dwelling units together into contracts in such a way that the sum of the expected bid prices is minimized. This report is intended to serve as a user's manual for staff members concerned with the problem of estimating lead-based paint abatement costs. Specific cases with respect to the preparation of cost estimates for individual dwelling units or of budget estimates for program managers, policy makers, or other decision makers, are treated.		14.
